Deviations in a draw of 59 from the 215 remaining refunds, 52 of which deviate

The distribution of the deviations in a draw of 59 (the sample size) from the 215 remaining refunds, 52 of which are dated before the last application of the customer's payments, as the sheet computes it (a hypergeometric distribution; the shaded range is the tightest with each tail below 5%). For draws in the highlighted 10 to 19 deviation range, about 93% of draws, the upper limit is approximately 27% to 44%, far above the 5% tolerable rate. A draw with no deviation has a 4.95% upper limit but is extremely unlikely, and its bar is a sliver, too thin to see. The test of the whole remainder establishes its observed deviation rate without sampling uncertainty.
